Guide: Disk Analyzer

What Disk Analyzer is

A visual explorer of used disk space, DaisyDisk/GrandPerspective-style — shows exactly which folders/files take up the most space on a disk, with instant drill-down into any subfolder.

How it works, under the hood

- When you pick a disk/folder, the app indexes it ONCE, completely, recursively — every file and subfolder, at any depth, in a single pass.
- The result is kept in an in-memory tree — every folder already knows its total size (the sum of all descendants).
- Once indexing finishes, entering any subfolder is instant (0 seconds) — the disk is never read again, you navigate the already-built tree.
- The tree stays in memory as long as the app is open — you can navigate back and forth as much as you like, with no rescanning.

Step by step

- Open Disk Analyzer in the sidebar.
- Pick the disk or folder to analyze from the list (main volume + any connected external disk).
- Wait for the initial indexing — a live counter shows how many files have been indexed so far, so you know the app is working, not stuck (can take from a few seconds to a few minutes depending on how many files the disk has).
- Once done, tap any segment in the colored bar or any row in the list to enter that folder — instantly.
- The top bar (breadcrumb) shows the full path taken — click any previous level to jump straight back there.

How to read the proportional bar

Each colored segment represents a file or folder at the current level, with a width proportional to its size relative to the rest of the content — the widest segment is the biggest space consumer. Hover over a segment for its exact name and size.

Deleting a file/folder

- Tap the trash icon next to any row in the list.
- The file/folder moves to the system Trash (recoverable, not permanent).
- If permissions deny the normal delete, the app automatically asks for the administrator password, once.
- The in-memory tree updates instantly after deletion — ancestor sizes decrease correctly, with no rescanning.
