Guide: System Tweaks

Advanced Finder

One button turns on 4 native macOS settings at once, useful for any editor:

- Show file extensions for ALL files (not just some) — useful to tell "project.drp" apart from "project.drp.bak".
- Show the Path Bar at the bottom of Finder windows.
- Show the Status Bar — free space, item count.
- Switch the default view to List View, the densest one for folders with many files.

Finder restarts automatically after applying — any open Finder window closes and reopens, that's expected.

Block .DS_Store on external / USB drives

macOS automatically writes a hidden ".DS_Store" file in every folder opened in Finder, to remember its appearance (icon positions etc.). On external/USB drives shared with other systems (Windows, other people), these files are useless and can be annoying. This tweak disables writing them on network and USB volumes — your external drives stay clean.

Spotlight Shield — per-disk/folder protection

Spotlight indexing on large project disks (video, archives) can waste resources for no reason — this module selectively protects any external disk or manually chosen folder.

- Check any connected external disk or manually added folder (" + Add folders...") to protect it — a marker file ".metadata_never_index" is written at its root, which Spotlight respects and no longer indexes it.
- Uncheck at any time to remove protection — the marker is deleted, normal indexing resumes.
- The green "Protected" badge next to each item clearly shows the real state, read directly from disk (never assumed).
- "Rescan" refreshes the list of currently connected disks + each one's real protection state.

Touch ID for sudo commands

Enables Touch ID/quick password for administrator (sudo) commands in Terminal — useful if you often work with the command line.

- Tap "Enable Touch ID for sudo commands" — modifies the system file `/etc/pam.d/sudo_local` (asks for the administrator password once).
- After enabling, restart Terminal to see the new Touch ID prompt on the next sudo command.
- If enabling fails, a small log automatically appears with the exact command sent and the system's exact response — useful for diagnosis, can be fully copied with "Copy all".
